General Description

The HV72 is a low-voltage serial to high-voltage parallel converters with push-pull outputs. It is especially suitable for use as a symmetric row driver in AC thin-film electroluminescent (ACTFEL) displays.

When the data reset pin (DR_{IO}) is at logic high, it will reset all the outputs of the internal shift register to zero. At the same time, the output of the shift register will start shifting a logic high from the least significant bit to the most significant bit. The DR_{IO} can be triggered at any time. The DIR and SHIFT pins control the direction of data shift through the device. When DIR is at logic high, DR_{IOA} is the input and DR_{IOB} is the output. When DIR is grounded, DR_{IOB} is the input and the DR_{IOA} is the output. See the Output Sequence Operation Table for output sequence. The POL and OE pins perform the polarity select and output enable function respectively. Data is loaded on the low to high transition of the clock. A logic high will cause the output to swing to V_{PP} if POL is high, or to GND if POL is low. All outputs will be in High-Z state if OE is at logic high. Data output buffers are provided for cascading devices.
